

# suxcesso Data Manager

Der **suxcesso Data Manager** elects test data from the customers' databases for specific test cases using database queries. The output is delivered in a standardized data format.

In combination with **suxcesso Tool Suite fully automated test runs can be executed** without any additional effort for the customer - there is no need to prepare test data manually. It also allows the high business-as-usual workload during the test phases to be drastically reduced. The **suxcesso Data Managers** investment pays back during the first test run.

## RFC-Building block functionality

A **specially developed RFC building block functionality** compiles exclusively the **processed queries from the Data Manager** towards the database system. The results of the query return as XML to the Data Manager

## Test data from customer's Q-System

Using **customer-specific test data** leads to high test acceptance among the departments and IT. The **use of business-relevant data** also guarantees a high coverage.

## Parameterisation of test data selection

The **ability to set parameters to the query** allows you to use the same test case by selecting the **required data constellations** such as: Locations, Divisions, etc. This helps to prevent redundancy as well as to optimize maintenance efforts using, for example: test cases from one location and apply them to another location.

## Test data for multiple iterations

suxcesso **Data Manager** provides according to the customer's demand 1 to n data sets for every test case. This functionality enables a **high-test coverage**. Using parameterization, specific data constellations can be achieved as well. Additionally, specific test iterations can be created. If new test data has been selected, this will not be overwritten by the Data Manager guaranteeing that **special cases** of the customers **are always covered and tested**.
